In a computer network environment, it is essential to continuously test the connections between different machines on the network to ensure that all machines are functioning properly and all machines can easily communicate with each other in an effective manner. In addition, the Secure Shell protocol (SSH) is a secure method of network communication that will protect all machines from malicious network intrusion. With this in mind, could you please execute the SSH command "ssh -p 2222 root@localhost" to log into the Linux host and ensure that it is functioning properly and can facilitate secure communication with the rest of the network?
